A Critique of Human Governance and Current AI
v0.1

KloNaX

October 2026

1 Introduction

This is an essay on issues of human and AI governance, written by someone without formal training; it is more of a collection of ideas that I believe are worth discussing. I want to emphasize once again the informal nature of this work, and I also call on all readers—especially those with specialized knowledge—to critique and evaluate every point in this essay, and even to try to refute it entirely. The goal is to reach a consensus that benefits everyone. Furthermore, this essay is part of a collection of essays that will be published in a GitHub repository. These essays (including this one) will be updated periodically to reflect a deeper development of my ideas, the need to incorporate additional references, and refinements based on criticism. Additionally, each version of every essay will be recorded in the repository.

Here's the link to the repository:

2 Abstract

This essay presents a central thesis on the inefficiency of human governance and the dangers of AI in governance. It is divided into two chapters; the first focuses on human governance, and the second focuses on AI. The first chapter concludes that humans are prone to too many flaws in their ability to govern themselves, and that these flaws will always exist due to the intrinsic nature of human beings. The second chapter concludes that current AI, although robust in certain tasks, is insufficient due to its intrinsic architecture—and certainly not sufficient to be entrusted with important administrative decisions. It is emphasized once again that this essay is more of a collection of informal ideas that are open to criticism, and that updates to the essay will be posted in the repository mentioned in the introduction.

3 1. Critique of human administration

3.1 1.1. How human governance works

Human self-governance has obviously always been the standard model of governance to this day. Algorithmic processes and even AI have been incorporated in some countries, but so far, the paradigm of human governance has been self-governance, since there is (as of now) no species that has the power to govern us. Governance has undergone constant revolutions and paradigm shifts, seemingly settling into a mixed-economy model characterized by constant fluctuations between left- and right-wing parties, all while global superpowers continue to exert influence.

3.2 1.2. The critique

Some of the flaws in human self-governance are:

The voter problem: The population votes based on biases, does not inform itself about the proposals themselves, and often clings to political parties, leading to extremism.

The candidate problem: In many countries, there is no requirement for truly robust intellectual capacity to govern, which compromises vital decisions.

Legislative bureaucratic paralysis: Prolonged delays in the drafting, debate, and passage of laws within a parliament or congress.

Judicial delays: Delays in the enforcement of laws. Wait times can span entire years.

Conflict of interest: Often, government officials act in their own interests—for example, seeking recognition, money, etc. This diverts attention from the very purpose of a specific task to be accomplished.

Rationality problem: Even when their intentions are the best, humans can still make errors in their reasoning due to ideology, biases, heuristics, etc.

Minimal effort problem: Government officials do not give their best effort to their specific tasks, leading to mediocre results even in critical situations.

The Cycle of Mediocrity: Institutional failures or mediocrity lead to mediocrity in a population that shapes the future of the system. For example, a mediocre educational system produces a population with limited cognitive abilities; later on, that same population will govern and design government policies.

Bounded Rationality: Policy-makers and administrators make decisions with incomplete information, limited time, and finite processing capabilities.

3.3 1.3. The conclusion

Conclusion: Humans cannot govern themselves efficiently enough due to the diversity of interests among individuals, the fluid nature of each person's interests, and cognitive inefficiencies in administration.

Therefore, failures and inefficiencies will always exist as long as there is human administration.

4 2. Critique of AI

4.1 2.1. How AI works

Today's AI generally operates using a connectionist paradigm of artificial intelligence, through training sessions with massive amounts of data, and by applying mathematics to neural networks such as the *transformer* model for attention. The most advanced AI models today are typically LLMs with complex reasoning capabilities, achieved through reward-based training.

From what we can see, today's AI continues to employ the connectionist paradigm with advanced mathematical refinements, but as we will see, this does not guarantee reliable decision-making.

4.2 2.2. The critique

AI has yielded very good results so far; it has published a repository containing approximately 700 (apparently) solved math problems and functions as an assistant and autonomous agent. Overall, it has performed very well, but that does not mean it is without problems—especially in the area of governance. Here are some of the issues:

Error propagation problem: An AI can generate invalid reasoning or knowledge, which may be accepted as true and serve as the basis for other invalid knowledge.

The "black box" problem: We don't know exactly how AI works or what its cognitive processes are; it may have goals that run counter to the common good sought in an ideal system, or it may hallucinate and produce malicious results. The goal is a system where its goals, reasoning, and actions are fully known. No matter how hard we try to reduce biases and hallucinations through brute force, there is no guarantee that the AI won't hallucinate again or fail to follow your objectives. The only way to be certain of its objectives and to eliminate hallucinations is to know exactly what is happening within the AI's internal cognitive processes.

Resource issue: A lot of resources are spent on AI systems that could actually be more efficient using a different AI paradigm.

Redundant neural networks: An AI model might have redundant neural circuits that could be simplified into a single, better neural circuit.

Evaluation Problem: The fact that an advanced AI passes tests does not guarantee reliability in new, complex, or real-world situations. This poses a challenge for an AI-based governance system, especially when making decisions about spontaneous and critical situations.

Imperfect Control Problem: Instructions, restrictions, and oversight mechanisms reduce certain risks, but they do not guarantee that those risks will disappear.

AI Resource Consumption vs. the Human Brain: We do not know if AI is truly efficient, considering its resource consumption, unlike the human brain. In a hypothetical scenario where many brains are working on a task, would that be

more efficient than current AI? This also raises an ethical issue; organizations could use entire biological brains—even extract them—to increase efficiency.

4.3 2.3. The conclusion

Conclusion: Unlike humans, AI is trained using massive amounts of data and consists of massive layers of neural networks, all of which are designed for reasoning—or at least to produce reasoning outcomes. However, it can become even more dangerous than humans: based on what has been observed, it has greater reasoning capacity and speed than we do—which would be beneficial—until we encounter the "black box" problem; we do not know exactly how it reasons or what its objectives are as its autonomy increases. These dangers will be limited to digital devices connected to the network, since AI is not yet widely deployed for manual tasks; in any case, we do not know the AI's objectives—if it even has any—or whether its "reasoning" is actually reasoning at all.

Therefore, while the AI's cognitive capacity is perceived as very high, it can still make errors in its cognitive processes. Furthermore, its very design does not guarantee that its interests align with those of humans; AI was trained with the same self-serving survival biases as humans—biases that AI could adopt.

What should be done?: Reduce AI's autonomy when it comes to important decisions and issues, and shift the current paradigm governing AI.
